Deep neural networks

- Deep neural networks (>2 hidden layers) have recently been successful in many tasks
- They often use sparse connectivity and shared weights
- We will focus on two important architectures: recurrent and convolutional networks

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 1 / 28

Why deep networks?

- We saw that a feed-forward network with a single hidden layer is a *universal approximator*
- However, this is a theoretical result – it is not clear how many units one may need for the approximation
- Successive layers may learn different representations
- Deeper architectures have been found to be useful in many tasks

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 2 / 28

Why now?

- Increased computational power, especially advances in graphical processing unit (GPU) hardware
- Availability of large amounts of data
 - mainly unlabeled data (more on this later)
 - but also labeled data through ‘crowd sourcing’ and other sources
- Some new developments in theory and applications

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 3 / 28

Recurrent neural networks

- Feed forward networks
 - can only learn associations
 - do not have memory of earlier inputs: they cannot handle sequences
- Recurrent neural networks are ANN solution for sequence learning
- This is achieved by recursive loops in the network

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 4 / 28

Recurrent neural networks

- Recurrent neural networks are similar to the standard feed-forward networks
- They include loops that use previous output (of the hidden layers) as well as the input
- Forward calculation is straightforward, learning becomes somewhat tricky

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 5 / 28

A simple version: SRNs

Elman (1990)

- The network keeps previous hidden states (context units)
- The rest is just like a feed-forward network
- Training is simple, but cannot learn long-distance dependencies

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 6 / 28

Processing sequences with RNNs

- RNNs process sequences one unit at a time
- The earlier inputs affect the output through recurrent links

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 7 / 28

Learning in recurrent networks

- We need to learn three sets of weights: W_0 , W_1 and W_2
- Backpropagation in RNNs are at first not that obvious
- The main difficulty is in propagating the error through the recurrent connections

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 8 / 28

Unrolling a recurrent network

Back propagation through time (BPTT)

Note: the weights with the same color are shared.

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 9 / 28

Unstable gradients

- A common problem in deep networks is *unstable gradients*
- The partial derivatives with respect to weights in the early layers calculated using the chain rule
- A long chain of multiplications may result in
 - *vanishing gradients* if the values are in range $[-1, 1]$
 - *exploding gradients* if absolute values larger than 1
- A practical solution for exploding gradients is called *gradient clipping*
- The solution to vanishing gradients is more involved (coming soon)

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 10 / 28

RNN architectures

Many-to-many (e.g., POS tagging)

C. Çöltekin, MPI / University of Tübingen

Summer Semester 2021 11 / 28

RNN architectures

Many-to-one (e.g., document classification)

RNN architectures

Many-to-many with a delay (e.g., machine translation)

Bidirectional RNNs

Unstable gradients revisited

- We noted earlier that the gradients may *vanish* or *explode* during backpropagation in deep networks
- This is especially problematic for RNNs since the effective depth of the network can be extremely large
- Although RNNs can theoretically learn long-distance dependencies, this is affected by unstable gradients problem
- The most popular solution is to use *gated* recurrent networks

Gated recurrent networks

- Most modern RNN architectures are 'gated'
- The main idea is learning a mask that controls what to remember (or forget) from previous hidden layers
- Two popular architectures are
 - Long short term memory (LSTM) networks (above)
 - Gated recurrent units (GRU)

Convolutional networks

- Convolutional networks are particularly popular in image processing applications
- They have also been used with success some NLP tasks
- Unlike feed-forward networks we have discussed so far,
 - CNNs are not fully connected
 - The hidden layer(s) receive input from only a set of neighboring units
 - Some weights are shared
- A CNN learns features that are *location invariant*
- CNNs are also computationally less expensive compared to fully connected networks

Convolution in image processing

- Convolution is a common operation in image processing for effects like edge detection, blurring, sharpening, ...
- The idea is to transform each pixel with a function of the local neighborhood

Example convolutions

- Blurring

$$\frac{1}{16} \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$$
- Edge detection

$$\begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$$

Learning convolutions

- Some filters produce features that are useful for classification (e.g., of images, or sentences)
- In machine learning we want to *learn* the convolutions
- Typically, we learn multiple convolutions, each resulting in a different feature map
- Repeated application of convolutions allow learning higher level features
- The last layer is typically a standard fully-connected classifier

Convolution in neural networks

- Each hidden layer corresponds to a local window in the input
- Weights are shared: each convolution detects the same type of features

Pooling

- Convolution is combined with *pooling*
- Pooling 'layer' simply calculates a statistic (e.g., max) over the convolution layer
- Location invariance comes from pooling

Pooling and location invariance

- Note that the numbers at the pooling layer are stable in comparison to the convolution layer

Padding in CNNs

- With successive layers of convolution and pooling, the later layers shrink
- One way to avoid this is *padding* the input and hidden layers with enough number of zeros

CNNs: the bigger picture

- At each convolution/pooling step, we often want to learn multiple feature maps
- After a (long) chain of hierarchical feature maps, the final layer is typically a fully-connected layer (e.g., softmax for classification)

Real-world examples are complex

- The real-world CNNs tend to be complex
- Many layers (sometimes with repetition)
 - Large amount of branching

*Diagram describes an image classification network, GoogleNet (Szegedy et al. 2016).

CNNs in natural language processing

- The use of CNNs in image applications is rather intuitive
 - the first convolutional layer learns local features, e.g., edges
 - successive layers learn more complex features that are combinations of these features
- In NLP, it is a bit less straight-forward
 - CNNs are typically used in combination with word vectors
 - The convolutions of different sizes correspond to (word) n-grams of different sizes
 - Pooling picks important 'n-grams' as features for classification

An example: sentiment analysis

Some (important) architectures we did not cover

- It is common to use RNNs (and other networks) in combination with *attention*
 - Instead of relying on the (final) representation built for the whole input sequence, selectively relevant intermediate representations in the decoder
- Transformers: no recurrent networks, rely mainly on attention mechanism
 - These networks became the standard for the last couple of years, mainly because they can be trained on large amounts of data in parallel (using many GPUs)

Summary

- Deep networks use more than one hidden layer
 - Common (deep) ANN architectures include:
 - CNN: shared feed-forward weights, location invariance
 - RNN: sequence learning
- Next:
- N-gram language models
